### ABSTRACT

Analyzing cyber incident data sets is an important method for deepening our understanding of the evolution of the threat situation. This is a relatively new research topic, and many studies remain to be done. In this paper, we report a statistical analysis of a breach incident data set corresponding to 12 years (2005–2017) of cyber hacking activities that include malware attacks. We show that, in contrast to the findings reported in the literature, both hacking breach incident *inter-arrival times* and *breach sizes* should be modeled by stochastic processes, rather Than by distributions because they exhibit autocorrelations. Then, we propose particular stochastic process models to, respectively, fit the inter-arrival times and the breach sizes. We also show that these models can predict the inter-arrival times and the breach sizes. In order to get deeper insights into the evolution of hacking breach incidents, we conduct both qualitative and quantitative trend analyses on the data set. We draw a set of cyber security insights, including that the threat of cyber hacks is indeed getting worse in terms of their frequency, but not in terms of the magnitude of their damage.

Keywords: Cyber hacking, Stochastic models, Cyber Security.

### **1. INTRODUCTION**

DATA breaches are one of the most devastating cyber incidents. The Privacy Rights Clearinghouse reports 7,730 data breaches between 2005 and 2017, accounting for 9,919,228,821 breached records. The Identity Theft Resource Center andCyber Scout reports1,093data breachincidents in 2016, which is 40% higher than the 780 data breach incidents in 2015. The United States Office of Personnel Management(OPM) reports that the personnel information of 4.2 million current and former Federal governmentemployees and the background investigation records of current, former, and prospective federal employees and contractors (including 21.5 million Social Security Numbers) were stolen in 2015. The monetary price incurred by data breaches is also substantial. IBM reports that in year 2016, the global average cost for each lost or stolen record containing sensitive or confidential information was \$158. NetDiligence.

Manuscript received November 22, 2017; revised March 16, 2018 and April 23, 2018; accepted April 28, 2018. Date of publication May 16, 2018; date of current version May 23, 2018. This work was supported in part by ARL under Grant W911NF-17-2-0127. The associate editor coordinating the review of this manuscript and approving it for publication was Prof. Mauro Conti. (Corresponding author: Shouhuai Xu.) M. Xu is with the Department of Mathematics, Illinois State University, Normal, IL 61761 USA. K. M. Schweitzer and R. M. Bateman are with the U.S. Army Research Laboratory South (Cyber), San Antonio, TX 78284 USA. S. Xu is with the Department of Computer Science, The University of Texas at San Antonio, San Antonio, TX 78249 USA (e-mail: shxu@cs.utsa.edu).

Color versions of one or more of the figures in this paper are available online at http://ieeexplore.ieee.org, reports that in year 2016, the median number of breached records was 1,339, the median per-record cost was \$39.82, the average breach cost was \$665,000, and the median breach cost was \$660,000.

### ISSN- 2394-5125 VOL 10, ISSUE 04, 2023

While technological solutions can harden cyber systems against attacks, data breaches continue to be a big problem. This motivates us to characterize the evolution of data breach incidents. This not only will deep our understanding of data breaches, but also shed light on other approaches for mitigating the damage, such as insurance. Many believe that insurance will be useful, but the development of accurate cyber risk metrics to guide the assignment of insurance rates is beyondthe reach of the current understanding data breaches (e.g., the lack of modeling approaches). Recently, researchers started modeling data breach incidents. Maillart and Sornette studied the statistical properties of the personal identity losses in the United States between year 2000 and 2008. They found that the number of breach incidents dramatically increases from 2000 to July 2006 but remains stable thereafter.

Edwards et al. analyzed a dataset containing 2,253 breach incidents that span over a decade (2005 to 2015). They found that neither the size nor the frequency of data breaches has increased over the years. Wheatley et al. analyzed a dataset that is combined from and and corresponds to organizational breach incidents between year 2000 and 2015. They found that the frequency of large breach incidents (i.e., the ones that breach more than 50,000 records) occurring to US firms is independent of time, but the frequency of large breach incidents occurring to non-US firms exhibits an increasing trend.

The present study is motivated by several questions that have not been investigated until now, such as: Are data breaches caused by cyber-attacks increasing, decreasing, or stabilizing? A principled answer to this question will gives a clear insightinto the overall situation of cyber threats. This question was not answered by previous studies.

Specifically, the dataset analyzed in only covered the time span from 2000 to 2008 and does not necessarily contain the breach incidents that are caused by cyber-attacks; the dataset analyzed in is more recent, but contains two kinds of incidents: negligent breaches (i.e., incidents caused by lost, discarded, stolen devices and other reasons) and malicious breaching.

Since negligent breaches represent more human errors than cyber-attacks, we do not consider them in the present study. Because the malicious breaches studied in contain four sub-categories: hacking (including malware), insider, payment card fraud, andunknown, this study will focus on the hacking sub-category (called hacking breach dataset thereafter), while noting that the other three subcategories are interesting on their own and should be analyzed separately.

### 2. LITERATURE SURVEY

1. Prior Works Closely Related to the Present Study:

Maillart and Sornette analyzed a dataset of 956 personal identity loss incidents that occurred in the United States between year 2000 and 2008. They found that the personal identity losses per incident, denoted by X, can be modeled by a heavy tail distribution  $Pr(X > n) \sim n - \alpha$  where  $\alpha = 0.7 \pm 0.1$ . This result remains valid when dividing the dataset per type of organizations: business, education, government, and medical institution. Because the probability density function of the identity losses per incident is static, the situation of identity loss is stable from the point of view of the breach size.

Edwards et al. analyzed a different breach dataset of 2,253 breach incidents that span over a decade (2005 to 2015). These breach incidents include two categories: negligent breaches (i.e., incidents caused by lost, discarded, stolen devices, or other reasons) and malicious breaching (i.e., incidents caused by hacking, insider and other reasons). They showed that the breach size can be modeled by the log-normal or log-skewnormal distribution and the breach frequency can be modeled by the negative binomial distribution,

#### ISSN- 2394-5125 VOL 10, ISSUE 04, 2023

Wheatley et al. analyzed an organizational breach incidents dataset that is combined from and and spans over a decade (year 2000 to 2015). They used the Extreme Value Theory to study the maximum breach size, and further modeled the large breach sizes by a doubly truncated Pareto distribution. They also used linear regression to study the frequency of the data breaches and found that the frequency of large breaching incidents is independent of time for the United States organizations, but shows an increasing trend for non-US organizations.

There are also studies on the dependenceamongcyber risks. Böhme and Kataria studied the dependence between cyber risks of two levels: within a company (internal dependence) and across companies (global dependence). Herath and Herath used the Archimedeancopula to model cyber risks caused by virus incidents, and found that there exists some dependence between these risks. Mukhopadhyay et al. used a copula-based Bayesian Belief Network to assess cyber vulnerability. Xu and Hua investigated using copulas to model dependent cyber risks. Xu et al. used copulas to investigate the dependence encountered when modeling the effectiveness of cyber defense early-warning. Peng et al. investigated multivariate cybersecurity risks with dependence.

Compared with all these studies mentioned above, the present paperis unique in that it uses a new methodologyto analyze a new perspective of breach incidents (i.e., cyber hacking breach incidents).

This perspective is important because it reflects the consequence of cyber hacking (including malware). The new methodology found for the first time, that both the incidents inter-arrival times and the breach sizes should be modeled by stochastic processes rather than distributions, and that there exists a positive dependence between them.

#### 2) Other Prior Works Related to the Present Study:

Eling and Loperfido analyzed a dataset from the point of view of actuarial modeling and pricing. Bagchi and Udo used a variant of the Gompertz model to analyze the growth of computer and Internet-related crimes. Condon et. al used the ARIMA model to predict security incidents based on a dataset provided by the Office of Information Technology at the University of Maryland. Zhan et al. analyzed the posture of cyber threats by using a dataset collected at a network telescope.

Using datasets collected at a honeypot, Zhan et al. exploited their statistical properties including long-range dependence and extreme values to describe and predict the number of attacks against the honeypot; a predictability evaluation of a related dataset is described in. Peng et al. used a marked point process to predict extreme attack rates. Bakdash et al. extended these studies into related cybersecurity scenarios.

Liu et al. investigated how to use externally observable features of a network (e.g., mismanagement symptoms) to forecast the potential of data breach incidents to that network. Sen and Borle studied the factors that could increase or decrease the contextual risk of data breaches, by using tools that include the opportunity theory of crime, the institutional anomie theory, and the institutional theory.

### **3. PROPOSED SYSTEM**

In this paper, we make the following three contributions. First, we show that both the hacking breach incident interarrival times (reflecting incident frequency) and breach sizes should be modeled by stochastic processes, rather than by distributions. We find that a particular point process can adequately describe the evolution of the hacking breach incidents inter-arrival times and that a

### ISSN- 2394-5125 VOL 10, ISSUE 04, 2023

particular ARMA-GARCH model can adequately describe the evolution of the hacking breach sizes, where ARMA is acronym for "AutoRegressive and Moving Average" and GARCH is acronym for "Generalized AutoRegressive Conditional Heteroskedasticity." We show that these stochastic process models can predict the inter-arrival times and the breach sizes.

To the best of our knowledge, this is the first paper showing that stochastic processes, rather than distributions, should be used to model these cyber threat factors. Second, we discover a positive dependence between the incidents inter-arrival times and the breach sizes, and show that this dependence can be adequately described by a particular copula. We also show that when predicting inter-arrival times and breach sizes, it is necessary to consider the dependence; otherwise, the prediction results are not accurate. To the best of our knowledge, this is the first work showing the existence of this dependence and the consequence of ignoring it. Third, we conduct both qualitative and quantitative trend analyses of the cyber hacking breach incidents.

We find that the situation is indeed getting worse in terms of the incidents inter-arrival time because hacking breach incidents become more and more frequent, but the situation is stabilizing in terms of the incident breach size, indicating that the damage of individual hacking breach incidents will not get much worse. We hope the present study will inspire more investigations, which can offer deep insights into alternate risk mitigation approaches. Such insights are useful to insurance companies, government agencies, and regulators because they need to deeply understand the nature of data breach risks.

### **5. CONCLUSION**

We analyzed a hacking breach dataset from the points of view of the incidents inter-arrival time and the breach size, and showed that they both should be modeled by stochastic processes rather than distributions. The statistical models developed in this paper show satisfactory fitting and prediction accuracies.

In particular, we propose using a copula-based approach to predict the joint probability that an incident with a certain magnitude of breach size will occur during a future period of time. Statistical tests show that the methodologies proposed in this paper are better than those which are presented in the literature, because the latter ignored both the temporal correlations and the dependence between the incidents inter-arrival times and the breach sizes.

We conducted qualitative and quantitative analyses to draw further insights. We drew a set of cybersecurity insights, including that the threat of cyber hacking breach incidents is indeed getting worse in terms of their frequency, but not the magnitude of their damage. The methodology presented in this paper can be adopted or adapted to analyze datasets of a similar nature.
